Greatest Common Divisor

$$(6, 12) \rightarrow 6$$

Euclid's algorithm

Fact:

$$\gcd(x, y) \overset{16}{\nearrow} \overset{12}{\nearrow} =$$

$$\gcd(y, x \overset{12}{\nearrow} \overset{4}{\nearrow} \bmod y)$$

$$x \geq y$$

pmf. [ sketch ]

$$x = \underline{q}y + \underline{r}$$

any number that divides  $x, y$ ,  $\Leftrightarrow$   $d$  also divides  $(y, r)$

$\Rightarrow$

$$\gcd(x, y) \geq \gcd(y, r)$$

$$\leq$$

$\downarrow$   
 $x \text{ mod } y$

Procedure  $\text{gcd}(x, y)$

//  $x \geq y$

if  $(y = 0)$  return  $x$  else if

else return  $\text{gcd}(y, x \text{ mod } y)$

Correctness? obvious

Time complexity?  $(x, y) \rightarrow (y, x \bmod y)$ .

~~174~~  $(12, 7) \rightarrow (7, 5)$

$$2n \cdot \Theta(n^2) = \Theta(n^3)$$

$$gcd \rightarrow O(n^3) \text{ time}$$

$$n \leftarrow \# \text{ bits of } x, y$$

Fact:

If  $\gcd(x, y) = d$ . then

$\exists$  integers  $a, b$  such that

$$ax + by = d.$$

Example:

$$\begin{aligned} 1 &= 2 \cdot 1 - 1 \cdot 1 \\ &= 1 \cdot 1 + 2 \cdot 1 - 2 \cdot 1 \\ &= 1 \cdot 1 + (2 - 2 \cdot 1) \cdot 1 \\ &= 1 \cdot 1 + 0 \cdot 1 \end{aligned}$$

$$\begin{aligned} 2 &= 2 \cdot 1 + 0 \\ 1 &= 1 \cdot 1 + 0 \cdot 1 \end{aligned}$$

$$\underline{1} = \underline{2} \cdot 1 - \underline{1} \cdot 1$$

$$\underline{3} = 1 \cdot \underline{2} + \underline{1}$$

$$1 = 2 \cdot 1 - \boxed{(3 - 1 \cdot \underline{2})} 1$$

$$= (2 \cdot 1 + 1 \cdot 2) - 3$$

$$= \underline{2} \cdot 2 - 3 \rightarrow (2, -1)$$

$$11 = 3.3 + \underline{2}$$

$$1 = \underline{2} \cdot 2 + (-1) \cdot 3$$

$$= (11 - 3 \cdot 3) \cdot 2 + (-1) \cdot 3$$

$$= 11 \cdot 2 + 3 [(-1) + -6]$$

$$= 11 \cdot 2 + 3(-7)$$

$$25 = 2 \cdot 11 + \underline{3}$$

$$1 = 11 \cdot 2 + \underline{3}(-7)$$

$$= 11 \cdot 2 + (25 - 2 \cdot 11)(-7)$$

$$1 = 11 \cdot \underbrace{16}_{(16, -7)} - 25 \cdot 7$$

$$1 = \underline{15} \cdot 25 - \underline{39} \cdot 11$$

proof  
of  
fact

$(x, y)$

$$\underbrace{a}_? x + \underbrace{b}_? y = d$$

$$(y, \underline{x \bmod y}) \quad \underline{a'y + b'(x \bmod y)} = d.$$

$$x = qy + (x \bmod y)$$

$$a'y + b'(x - qy) = d$$

$$\boxed{y(\underbrace{a' - qb'}_{\parallel b}) + \underbrace{b'}_{\downarrow a} x = d} \quad \square$$

# Exponentiation / Powering

$a, b, N \leftarrow n\text{-bit numbers (}\pm\text{ve integers)}$

$$(a^b \bmod N)$$

$$(a * a) \bmod N, \dots, (a^{b-1} \bmod N) \rightarrow$$

$$O(b) \Theta(n^2)$$

$\text{poly}(n)$

$$(2^{20})^{\underline{\underline{2^{100}}}} \bmod (2^{50})$$

$$a * a \bmod N \rightarrow a^2 \bmod N$$

$$\left( \underline{a^2 \bmod N} * \underline{a^2 \bmod N} \right) \bmod N \rightarrow a^4 \bmod N.$$

$$\vdots$$

$$\left( a^{2^i} \bmod N \right) \rightarrow i \text{ steps}$$

What if  $b$  is not a perfect power of 2?

$$\begin{array}{c}
 \text{1001} \\
 \text{---} \quad \downarrow \\
 (a^0 \text{ not } N, \overbrace{a^1 \text{ not } N, a^2 \text{ not } N, a^4 \text{ not } N}^{\text{not } N})
 \end{array}$$
  

$$\begin{array}{c}
 a^{1001} = a^{1000} \cdot a^1 \\
 \left( \begin{array}{c} \downarrow \quad \downarrow \\ \text{not } N \end{array} \right)
 \end{array}$$

Procedure Power ( $a, b, N$ )  
//  $a, b, N$  are  $k$ -indexed  $k$ -bit numbers.  
result  $\leftarrow 1$

factor  $\leftarrow a$

for  $j = 1$  to  ~~$n$~~   $n$

if ( $b[j] = 0$ )

factor  $\leftarrow$  (factor \* factor)  
mod  $N$ .

Continue

else

~~factor~~

result  $\leftarrow$  (result \* factor) mod  $N$

$factor \leftarrow (factor * factr) \text{ mod } n.$   
 end if  
 return result

Correctness: Obvious.

Time complexity?  $\Theta(n) \Theta(n) = \Theta(n^2) \rightarrow \underline{\underline{\Theta(n^2)}}$   
 $= \Theta(n^2) \approx 2^{10} n$

Remarks

$N$ , # bits =  $\Theta(n)$

$$2^{100} \rightarrow 100 \quad \equiv \quad n \approx \log N.$$

Primality Testing.

$N$   $(\times N)$   
 $2 \times ?$

$\text{poly}(N)$   
 $\downarrow$   
 $\text{poly}(\log N)$

$$O(\sqrt{N}) = O(2^{n/2})$$

$$O(\log^3 n)$$
